System: Marine_freshwater_brackish

Kingdom	Phylum	Class	Order	Family
Animalia	Chordata	Actinopterygii	Perciformes	Gobiidae

Common name trident goby (English), Oriental goby (English), striped goby (English), polosatyi trekhzubyi bychok (Russian, Russian Federation), Chameleon goby (English), Japanese goby (English), shimahaze (Japanese, Japan), striped tripletooth goby (English, Russian Federation), shimahaze (Japanese)

Synonym *Gobius fascipectoralis* , Fowler, 1938
Triaenophorichthys taeniatus , Gunther, 1874
Triaenophorichthys trigonocephalus , Gill, 1859
Triaenophorus trigonocephalus , Gill, 1858
Tridentiger bifasciatus , Steindachner, 1881
Tridentiger bucco , Jordan and Snyder, 1901
Tridentiger taeniatus , Reeves, 1927
Tridentiger trigonocephalus , Rendahl, 1924
Trifissus ioturus , Jordan & Snyder, 1900
Triaenophorus trigonocephalus

Similar species

Summary Treidentiger trigonocephalus (the chameleon goby) is a native fish of Asia which is spread through ship ballast water or via eggs laid on hulls. It has established in California and Australia where it has been introduced. The main impact of this species is thought to be competition with native species.

[view this species on IUCN Red List](#)

Species Description

The Chameleon goby is a grey-brown coloured goby with a white speckled head and two characteristic black stripes (Hayes *et al.* 2005). The stripes go from behind the eye to the tail fin and from the snout along the upper portion of pectoral fin to the tail fin. It is able to mask the black stripes by changing its colour to a grey-brown. There are two dorsal fins, which often have brown horizontal stripes and scattered white spots. The anal fin has a grey to orange stripe along the middle (NIMPIS 2006). Adult can grow to 120mm in length (NIMPIS 2006). Eggs are somewhat pointed at one end (Breder and Rosen 1966, in FishBase 2006). There is a cluster of adhesive filaments at basal pole and the yolk is yellowish; with the late embryo pigmented on hindgut and ventral margin of tail (Watson 1996, in FishBase 2006).

Lifecycle Stages

Chameleon gobies are relatively short-lived, reaching sexual maturity within one year and living up to three years.

Habitat Description

Chameleon goby can live in freshwater, brackish and marine habitats, including artificial habitats. It lives in shallow water on (or near) the bottom, under rocks, in burrows, or in crevices (NIMPIS 2006). This bottom dweller may find a home in seagrass meadows (Kwak 2003). In its native range, the Chameleon goby is typically found in rocky areas of coastal bays and in freshwater (Fishbase 2006). In its introduced range in Australia it is found in both brackish and saltwater, while in USA it is found in brackish and freshwater environments (Fishbase 2006).

Reproduction

Male and female Chameleon goby are separate, and eggs are laid during spring and summer. Eggs are deposited in nests which are guarded by the male (Breder and Rosen 1966, in FishBase 2006). Eggs take nine to 10 days to hatch. Females are able to spawn up to 10 times within a breeding season, which is from March through to November in the USA (FishBase 2006). In Japan, temperatures during the breeding season are between 18°C to 26°C.

Nutrition

The Chameleon goby mostly takes its prey from within the sediment and may consume large numbers of polychaetes, feeding mainly at night (Kwak 2003). Stomach contents have also been found to include crab larvae and caprellid amphipods (Kwak 2003).

General Impacts

Chameleon goby have specific habitat requirements and it is therefore possible that they will compete with species sharing their preferred habitat (NIMPIS 2006).

Management Info

Preventative measures: A two year study was undertaken for the Department of Environment and Heritage (Australia) by the Commonwealth Scientific and Industrial Research Organisation (CSIRO) to identify and rank introduced marine species found within Australian waters and those not found within Australian waters. All of the non-native potential target species identified in this report are ranked as high, medium and low priority, based on their invasion potential and impact potential. *Tridentiger trionocephalus* is identified as one of ten potential domestic target species most likely to be spread to uninfected bioregions by shipping. A hazard ranking of potential domestic target species based on invasion potential from infected to uninfected bioregions identifies *T. trionocephalus* as a 'low priority species' - these species have a low impact potential and a low invasion potential relative to the other domestic non-native species identified in the report.

For more details, please see [Hayes et al. 2005](#).

The rankings determined in Hayes et al. 2005 will be used by the National Introduced Marine Pest Coordinating Group in Australia to assist in the development of national control plans which could include options for control, eradication and/or long term management.

Pathway

Fertilised eggs of *T. trionocephalus* may have been transported along with Pacific oysters in commercial shipments (Hayes et al. 2005). Many introduced marine species are first recorded from regions with commercial ports and it is believed the large amounts of ballast water carried by international shipping is the most common way introduced marine species are transported (Carlton 1985, in The eggs of *T. trionocephalus* may be transported attached to fouling organisms on vessel hulls (Hayes et al., 2005).

Trinational Risk Assessment Guidelines for Aquatic Alien Invasive Species. Commission for Environmental Cooperation. 393, rue St-Jacques Ouest, Bureau 200, Montréal \(Québec\), Canada. ISBN 978-2-923358-48-1.](#)

Summary: In 1993, Canada, Mexico and the United States signed the North American Agreement on Environmental Cooperation (NAAEC) as a side agreement to the North American Free Trade Agreement (NAFTA). The NAAEC established the Commission for Environmental Cooperation (CEC) to help the Parties ensure that improved economic efficiency occurred simultaneously with trinational environmental cooperation. The NAAEC highlighted biodiversity as a key area for trinational cooperation. In 2001, the CEC adopted a resolution (Council Resolution 01-03), which created the Biodiversity Conservation Working Group (BCWG), a working group of high-level policy makers from Canada, Mexico and the United States. In 2003, the BCWG produced the Strategic Plan for North American Cooperation in the Conservation of Biodiversity. This strategy identified responding to threats, such as invasive species, as a priority action area. In 2004, the BCWG, recognizing the importance of prevention in addressing invasive species, agreed to work together to develop the draft CEC Risk Assessment Guidelines for Aquatic Alien Invasive Species (hereafter referred to as the Guidelines). These Guidelines will serve as a tool to North American resource managers who are evaluating whether or not to introduce a non-native species into a new ecosystem. Through this collaborative process, the BCWG has begun to implement its strategy as well as address an important trade and environment issue. With increased trade comes an increase in the potential for economic growth as well as biological invasion, by working to minimize the potential adverse impacts from trade, the CEC Parties are working to maximize the gains from trade while minimizing the environmental costs.
