**Common name**

wedge clam (English), Atlantic rangia (English), common rangia (English)

**Synonym**

**Similar species**

**Summary**

Rangia cuneata clams inhabit low salinity estuarine habitats and are, as such, most commonly found in areas with salinities from 5-15 PSU. Along the Mexican Gulf coast, they form the basis for an economically important clam fishery. A combination of low salinity, high turbidity and a soft substrate of sand, mud and vegetation appears to be the most favourable habitat for Rangia cuneata. The species has recently been found in European brackish waters. After initially finding only a few small individuals in 2005, R. cuneata was encountered frequently in the pipes of the cooling water system of an industrial plant from February 2006 onwards. Before this present record, R. cuneata was only known from the Gulf of Mexico and the Atlantic coast of North America.

*view this species on IUCN Red List*

**Species Description**

The valves of *Rangia cuneata* are thick and heavy, with a strong, rather smooth pale brown periostracum. The shells are equivalent, but inequilateral with the prominent umbo curved anteriorly. An external ligament is absent or invisible, but the dark brown internal ligament lies in a deep, triangular pit immediately below and behind the beaks. Both valves have two cardinal teeth, forming an inverted V-shaped projection. The upper surface of the long posterior lateral teeth (LaSalle and de la Cruz 1985) is serrated. The inside of the shell is glossy white, with a distinct, small pallial sinus, reaching to a point halfway below the posterior lateral. The pallial line is tenuous (Garcia-Cubas 1981).

**Lifecycle Stages**

In the USA, *Rangia cuneata* has two spawning periods ranging from March-May and late summer-November in Louisiana (Fairbanks 1963) and February-June and September-November in Mexico (Rogers and Garcia-Cubas 1981), although in both areas, spawning may be continuous. Cain (1975) found that gametogenesis was initiated when the water temperature rose above 15 °C and with salinities above 0 PSU or below 15 PSU (Hopkins 1970).
Habitat Description

*Rangia cuneata* inhabits low salinity estuarine habitats (Parker 1966) and is as such most commonly found in areas with salinities from 5-15 PSU (Swingle and Bland 1974). *R. cuneata* possess both extracellular (blood and body fluid) and intracellular mechanisms of osmoregulation, which enables them to respond to sudden salinity changes in many estuaries (Bedford and Anderson 1972). They can cross the 'horohalinicum', the 5-8 PSU salinity boundary which usually divides fresh and salt-water invertebrates, making them one of the few freshwater clams to become established in brackish water (Ladd 1951) as such thriving in a zone unfavourable for many animals. Competition and predation may explain its scarcity in high salinity environments (Cooper 1981). A combination of low salinity, high turbidity and a soft substrate of sand, mud and vegetation appears to be the most favourable habitat for *R. cuneata* (Tarver 1972). Although larvae prefer coarser sediment for settlement, adults are often found in muddy sediments (Fairbanks 1963; Cain 1975; Jordan and Sutton 1984).

Nutrition

*Rangia cuneata* is a non selective filter-feeder, turning large quantities of plant detritus and phytoplankton into clam biomass (Darnell 1958) but the species also appears to obtain organic matter and phosphate from the sediment by direct ingestion or by feeding on bacteria associated with these materials (Tenore *et al.* 1968).

General Impacts

Verween *et al.* (2006) describe *R. cuneata* as a biofouling species, causing problems in industrial cooling water systems.

Management Info

We have not recorded any management information for this species.

Pathway

Rangia may owe its reappearance on the U.S. Atlantic coast to the transportation of *Crassostrea virginica* from the Gulf of Mexico to Chesapeake Bay (Pfitzenmeyer and Drobeck 1964)

Summary: A population of Rangia cuneata (G. B. Sowerby I, 1831), an estuarine bivalve, has been recorded in the harbour of Antwerp, Belgium. This species is new to the European brackish water fauna. After initially finding only a few small individuals in August 2005, R. cuneata was encountered frequently in the pipes of the cooling water system of an industrial plant from February 2006 onwards. Before this present record, R. cuneata was only known from the Gulf of Mexico and the Atlantic coast of North America.
