Charybdis japonica **System:** Marine_terrestrial

Kingdom	Phylum	Class	Order	Family
Animalia	Arthropoda	Malacostraca	Decapoda	Portunidae

Common name Asian crab (English), paddle crab (English), Asian paddle crab (English), swimming crab (English), blue crab (English)

Synonym

Similar species

Summary The Asian paddle crab *Charybdis japonica* is a portunid (swimming) crab native to marine environments of Central and South East Asia. It may impact native esturine communities by competing for space and resources with native crabs. As it transmits disease and preys on native shellfish it is a potential threat to fisheries and traditional shell-fishing.

view this species on IUCN Red List

Species Description
Charybdis japonica have a carapace width of up to 12cm (Gust *et al*. 2003). They have a pilose (hairy) carapace (although amount of hair varies to little or none). The carapace has ridges with six frontal teeth, triangular and sharp. The inner supraorbital lobe is broadly triangular (Smith *et al*. 2003). Wee and Ng (1995) record the colour of *C. japonica* in Japan as mottled cream and purple. In the Waitemata harbour (New Zealand) specimens varied from pale green and off-white, through olive green to a deep chestnut with purplish markings on the carapace and upper surfaces of the appendages (Smith *et al*. 2003). In addition, most Waitemata specimens have yellow-orange markings, some with only a hint of yellow-orange and some with very noticeable brown-orange on parts of the carapace and the legs, especially on the chelae where the upper colouration grades into the white to off-white ventral surfaces (Smith *et al*. 2003).

Notes
\"Charybdis\" is Greek for whirlpool.

Uses
This crab is found and exploited in Asia where it is trapped using pots and gill nets (Archdale *et al.* 2006).

Habitat Description
In Korea, juvenile *C. japonica* (<25mm carapace width W) are abundant in eelgrass (*Zostera marina*) meadows (Huh and An 1998, in Smith *et al*. 2003), but there are few other accounts of their distribution and habits in wild populations. In Auckland (New Zealand) it is found in estuarine habitats comprised of ‘firm sand-muddy fine sand flats’ or ‘muddy-shelly fine sand’ habitats (Gust and Inglis 2006).

Reproduction
Wang *et al*. (1996) report a bimodal reproductive season in China, with spawning in spring and autumn when sea temperatures are between 20°C and 28°C. Females lay an average of c. 85 000 eggs per brood (Wang *et al*. 1996, Smith *et al*. 2003) and may produce multiple broods in a single year.

Nutrition
This large crab is known to be an opportunistic predator of bivalves, fish, cephalopods and other benthic invertebrates (Jiang *et al*. 1998, in Smith *et al*. 2003).

General Impacts
Disease transmission is one of the key potential impacts of the paddle crab in introduced environments. *C. japonica* is known to be a host or carrier of the White Spot Syndrome Virus (WSSV) (Maeda *et al*. 1998, in *Potential next pests* 2003). WSSV is a serious fisheries threat as it infects a broad spectrum of crustaceans, and can cause cumulative mortalities of up to 100% within 3 to 10 days from the first sign of disease (Lightner 1996, in *Potential next pests* 2003).

Management Info
Preventative measures: A two year study was undertaken for the Department of Environment and Heritage (Australia) by the Commonwealth Scientific and Industrial Research Organisation (CSIRO) to identify and rank introduced marine species found within Australian waters and those not found within Australian waters, categorised *C. japonica* as one of ten most likely invaders using the most influential measure of environmental similarity and one of ten potentially most damaging species. *C. japonica* is catergorised as a 'Medium High Priority' species based on its invasion potential/impact. These rankings will be used by the National Introduced Marine Pest Coordinating Group in Australia to assist in the development of national control plans. See Hayes *et al.* 2005 for full details.
Physical: For eradication and exploitation purposes Archdale *et al.* (2006) examined the performance of two pots commonly used in Japan to catch the crab : a box-shaped pot with slit entrances and a dome-shaped pot with open funnel entrances. The latter was found to be 100% efficient while the box-shaped box was only 66% efficient.
Swimming crabs are known to be highly sensitive to saccharides, in response to which they show strong food searching behaviour (Kawamura *et al*. 1995). Kawamura and collegues conducted a study to examine the possibility of using sugarcane as an attractant in basket traps for *Charybdis japonica* during their reproductive season and found that a bait combination of sugarcane and fish was found more effective than fish bait alone, whereas sugarcane alone was ineffective.

Pathway
The paddle crab may have been introduced from ship ballast water (Gust *et al*. 2003). This is known to be a potential route of spread of the Asian paddle crab.
