

Boa constrictor imperator

System: Terrestrial

Kingdom	Phylum	Class	Order	Family
Animalia	Chordata	Reptilia	Squamata	Boidae

Common name common boa constrictor (English, Puerto Rico), common northern boa (English), central American boa (English), Colombian boa (English), Colombian redtail boa (English), boa (Spanish), boa constrictora (Spanish), boa colombiana (Spanish)

Synonym *Boa constrictor imperator*, Daudin, 1803
Boa imperator, Daudin, 1803
Boa eques, Eydoux & Souleyet, 1842
Boa imperator, Dumeril & Bibron, 1844
Boa eques, Dumeril & Bibron, 1844
Boa constrictor ithsmica, Garman, 1883
Boa diviniloquax mexicana, Jan, 1863
Boa imperator, Boulenger, 1893
Boa mexicana, Boulenger, 1893
Boa constrictor imperator, Forcart, 1951
Boa constrictor imperator, Stimson, 1969
Constrictor constrictor imperator, Ihering, 1911
Constrictor constrictor sigma, Smith, 1943

Similar species *Boa constrictor amarali*, *Boa constrictor constrictor*, *Boa constrictor longicauda*, *Boa constrictor melanogaster*, *Boa constrictor mexicana*, *Boa constrictor nebulosa*, *Boa constrictor occidentalis*, *Boa constrictor orophias*, *Boa constrictor ortonii*, *Boa constrictor sabogae*

Summary The common *Boa constrictor imperator* is a top nocturnal predator that kills its prey by constriction. Although it prefers small mammals such as rodents and bats, it also eats birds, amphibians, lizards, iguanas, and other snakes. It may thrive in forested areas, savannahs, cultivated sites, and suburbs. It exhibits both terrestrial and arboreal habits. It may enter caves to catch bats on flight. This species represents a threat to humans, particularly small children. It may affect agricultural activities. For example, causing damage to chicken farms. It threatens native species of amphibians, birds, lizards, snakes, and bats. It may even outcompete the two native boa species: the Puerto Rican boa *Epicrates inornatus* and the Mona Island boa *Epicrates monensis*, which are smaller in size than the common boa constrictor.

GLOBAL INVASIVE SPECIES DATABASE

FULL ACCOUNT FOR: *Boa constrictor imperator*

Species Description

While neonates range from 18-22 inches long, adult Boa may measure more than 30 feet. Adult females are larger than adult males. *Boa constrictor imperator* is ranked as one of the largest species of snake in the world due to its maximum growth potential being between 4 and 5 meters in length. Naturally, they show a characteristic pattern of some 30 brown or reddish dorsal patches or "saddles" on a lighter background, although the pet industry have developed a variety of "morphs" with a number of different colorations and patterns, including albinos. Some individuals have prominent dark markings on the tail. This subspecies also includes a number of isolated dwarf populations which are also being exploited by the pet trade. They differ in appearance depending on whether they live on mainland or island. Island boas tend to have longer, more narrow heads occupying large eyes. In addition, island males have considerably longer tails than those of the mainland boas (Boback, 2005; Quick *et al*, 2005).

Notes

It is a CITES Appendix II species.

Lifecycle Stages

Most specimens in captivity live about 10 years, but 40-year old specimens have been recorded. Males reach sexual maturity at their third month of age, but females must reach three years before they can breed successfully. Being ovoviviparous, they produce 20-50 live hatchlings after a 110-150 days gestation period (Reed, 2005).

Uses

The international pet trade has turned the common boa constrictor, including its dwarf varieties, into a valuable merchandise. It has developed various morphs with different colors and patterns which are assigned high prices. In its native range it is sometimes collected to make folk medicines (Reed, 2005).

Habitat Description

Various populations of this subspecies occupy a wide variety of habitats: desert, tropical forest, savannah, and small tropical islands, both continental and oceanic, from sea level to moderate elevations. Human presence have forced them to adapt to live in cultivated sites, and even in suburbs. They exhibit both terrestrial and arboreal habits, and they enter and establish themselves in caves in pursuit of bats (Romero-Najera *et al*, 2007; Quick *et al*, 2005; Garza, 1995-2008).

Reproduction

Sexual and ovoviviparous. Females can breed at their third year of age, and then can produce 20-50 live hatchlings after a 110-150 days gestation period. The maximum litter size is recorded as being 60 hatchlings after one gestation period. Neonates lead independent lives from birth (Reed, 2005; Areste & Cebrian, 2003).

Nutrition

Boa constrictor imperator is strictly a carnivore, however, the range of fauna consumed is diverse. Diet includes birds, bats, reptiles, and mammals ranging in size depending on the size of the *B. constrictor imperator* (Quick *et al*, 2005; Reed, 2005).

General Impacts

Common boas are considered a threat to endemic vertebrates and carnivores that can be consumed once *Boa constrictor imperator* reaches adult size. It is feared that they may outcompete the smaller native boas: the 'Near Threatened (NT)' Puerto Rican boa (see [Epicrates inornatus in IUCN Red List of Threatened Species](#)), the Mona Island boa *Epicrates monensis monensis* and the Virgin Island tree boa *Epicrates monensis granti*. Boas are also a threat to humans, specifically to small children, pets and small farm animals. The increase in world trade of reptiles in the past 10 years could pose problems due to the ticks that many of them carry, which could pass diseases to domesticated livestock populations (Burridge & Simmons, 2003; Cuarón *et al.*, 2004).

Management Info

Preventative measures: Risk Assessment models for assessing the risk that exotic vertebrates could establish in Australia have been further explored by the Western Australia Department of Agriculture & Food (DAFWA) to confirm that they reasonably predict public safety, establishment and pest risks across a full range of exotic species and risk levels.

The [Risk assessment for the Boa \(*Boa constrictor*\)](#), has been assigned a VPC Threat Category of **EXTREME**. Mammals and birds were assessed for the pest risk they pose if introduced to Australia, by calculating Vertebrate Pests Committee (VPC) Threat Categories. These categories incorporate risk of establishing populations in the wild, risk of causing public harm, and risk of becoming a pest (eg causing agricultural damage, competing with native fauna, etc). The 7-factor Australian Bird and Mammal Model was used for these assessments.

Pathway

Boa constrictor imperator is frequently introduced by domestic trade as they are extremely common exotic pets. During the years 1989 through 2000, 115,131 *Boa constrictor* individuals were recorded as imported into the United States (Reed, 2005).

Summary: This report documents work contributing to a project commissioned by the Invasive Animals Cooperative Research Centre to validate and refine risk assessment models used in decisions to import and manage introduced vertebrate species. The intent of the project was to: a) increase predictive accuracy, scientific validation and adoption of risk assessment models for the import and keeping of exotic vertebrates, and b) reduce the risk of new vertebrate pests establishing introduced populations in Australia.
