Common name feral horse (English), horse (English)

Synonym

Similar species

Summary *Equus caballus* is a large non-ruminant herbivorous mammal that is not dissimilar in appearance to the domestic horse. *E. caballus* has an average lifespan of 25 - 30 years, with 20 years of sexual activity. While preferred habitat is open grasslands, *E. caballus* has been also known to invade desert, semi-desert plains, coastal areas, subalpine regions, tropical savannah grasslands, forests, scrublands and wetlands. In some regions they are protected as they are seen as a valuable asset, but in other places they are considered a pest, as they compete with livestock for resources, degrade plant habitats by grazing and trampling, contaminate water sources, damage fences and decrease native biodiversity.

Species Description

The feral horse, *Equus caballus*, is morphologically similar to the domestic horse, standing an average of 1 - 1.6 m high at the shoulder and weighing 350 - 450 kg. General appearance is variable, including coat colour that ranges from black, brown, tan and white to white with patches of orange or brown. Coat hairs are short and fine, tail is relatively short and there is hair present on the forehead (forelock) and along the neck (mane). The average lifespan of *E. caballus* is 25 - 30 years. (Csurhes *et al.* 2009).

Notes

In the Australian Alps, foxes, hares (*Lepus europaeus*), house mice ([Mus musculus](#)), feral horses (*Equus caballus*) and weeds have all increased their presence at higher altitudes most likely due to changes in climate (Green and Pickering 2002).

Habitat Description

While preferred habitat is open grasslands, *Equus caballus* has been also known to invade desert, semi-desert plains, coastal areas, subalpine regions, tropical savannah grasslands, forests, scrublands and wetlands.

General Impacts

Equus caballus is a grazer, feeding on approximately 2–2.5% of its bodyweight in plant matter per day. This grazing, along with trampling, contributes to decreases in native plant biodiversity, and can also fracture saturated turf. This can lead to increased opportunity for weed establishment, soil erosion and water ponding. Soil compaction can be another issue. Changes in community composition related to feral horse populations have been observed for fish, birds, small mammals, reptiles, crabs and ants. Feral horses compete with livestock for resources, can damage fences and water bodies and can foul water sources through fecal contamination. They can also harbour exotic diseases, such as equine influenza, and may introduce and spread weeds via seed present in fecal matter, manes and tails. (Csurhes *et al.* 2009; Department of the Environment and Heritage 2004; Nimmo & Miller 2007).

Management Info

Control methods include fertility control, capturing excess animals and offering adoption, shooting - both ground shooting and aerial via helicopters, trapping, and mustering. (Csurhes *et al.* 2009; Department of the Environment and Heritage, Australia 2004; Nimmo & Miller 2007).
