Similar species *Wisteria sinensis*, *Wisteria frutescens*

Summary In its alien range, *Wisteria floribunda* is still used as an ornamental and often escapes from landscapes and becomes invasive in natural ecosystems. *Wisteria floribunda* infests forest edges and disturbed areas, including riparian zones and tolerates shade and a variety of soil types. In riparian areas, *Wisteria floribunda* spreads downstream as seeds float to new locations.

Species Description

According to Martin (2002), *Wisteria floribunda* is a perennial vine that can live for 50 years or more and can grow up to 38cm in diameter. Leaves are alternate and pinnately compound; they are up to 30cm long and consist of 13-19 leaflets. Flowers hang in clusters that sometimes exceed 40cm in length. Flower colour is usually blue-violet but other cultivars (which may be escaped plants) are white, purple, pink, and lavender. Flowers are usually produced from April to May in the United States. Seedpods are 10-15cm in length, hairy, brown, narrow at the base, and constricted between seeds. *W. floribunda* twines clockwise around host plants.

Notes

The seeds and pods of *Wisteria floribunda* are toxic if ingested and may cause nausea, vomiting, stomach pains, and diarrhea (Martin, 2002). *Wisteria floribunda* is not as widespread in the United States as its brother vine, *W. sinensis*, which has caused problems throughout the eastern U.S.

Uses

Wisteria floribunda has been commonly used as an ornamental since 1830 when it was first introduced (Remaley, 1999). Martin (2002) notes that it has been grown extensively in the United States for ornamental uses on porches, gazebos, walls, and gardens. Many alternatives to this vine exist, including American wisteria (*Wisteria frutescens*), Trumpet creeper (*Campsis radicans*), Trumpet honeysuckle (*Lonicera sempervirens*), Dutchman's pipe/pipevine (*Aristolochia macrophylla*), and Crossvine (*Bignonia capreolata*).

Habitat Description

Typically, *Wisteria floribunda* infests forest edges and disturbed areas (Martin, 2002). Remaley (1999) notes that it grows best in full sun but is shade-tolerant. *W. floribunda* can tolerate a variety of soil and moisture types but it prefers loamy, deep, well drained soils.

Reproduction

According to Remaley (1999), vegetative reproduction is the primary means of expansion for *Wisteria floribunda*. In its preferred habitat, however, seeds may be produced, and in riparian areas they may be carried downstream for long distances.

General Impacts

According to Remaley (1999), native shrubs are overtaken by *W. floribunda* through strangling and shading. Even larger trees can be killed by this vine, causing large gaps in the canopy when they fall; this open canopy furthers the growth of *W. floribunda*. This aggressive vine may form dense thickets allowing little else to grow.

Management Info

Physical: According to Martin (2002), current management approaches consist of mechanical and chemical methods. Mechanical methods should be used for small populations or where herbicides could damage desirable species. When cutting vines, cut close to the root collar to discontinue growth of existing vines and reduce seed production. *W. floribunda* will resprout, so it is recommended that the vine be cut repeatedly every two weeks from early in the growing season to autumn. Vines should be removed because they may continue to grow and girdle the host plant. Try to remove the entire plant (including roots) and dispose of all parts because any plant parts left can resprout.

Chemical: Cut-stump herbicide applications should be used where there are large stands of established vines or where desirable plants occur and could be affected by foliar spray. Cut the vine close to the ground and apply glyphosate or triclopyr (25% solutions in water) to the cut area. If resprouting occurs retreatment may be necessary. This treatment is not effective if the ground is frozen. Foliar sprays should be used where mechanical controls would be disruptive and cut-stump methods are impractical, but additional precautions should be taken not to harm non-target species. Spray the foliage thoroughly, but do not apply so much that it drips off. Application may be more effective in warmer temperatures (above 15-18 C) because translocation is slower in cooler weather. Triclopyr is specific for control of broadleaved plants and may be beneficial if protection of valuable native grasses is of concern. Glyphosate is non-selective and should be used with care. Chlopyralid targets aster, buckwheat, and the pea family. However, chlopyralid can seep into groundwater in sandy and limestone soil types. Picloram may provide control in areas where desirable vegetation is not present.

Pathway

W. floribunda is a popular ornamental (Martin, 2002).
