Pylodictis olivaris 正體中文

System: Terrestrial

Kingdom	Phylum	Class	Order	Family
Animalia	Chordata	Actinopterygii	Siluriformes	Ictaluridae

Common name mud cat (English), shovelhead cat (English), opelousas (English), yellow cat (English)

Synonym
Opladelus olivaris
Silurus olivaris
Hopladelus olivaris
Pelodichthys olivaris
Leptops olivaris

Similar species

Summary Pylodictis olivaris is one of the largest members of the catfish family and its introduction is the most biologically harmful of all fish introductions in North America as it predates heavily on native fish. Native to the warm water streams and rivers of the Mississippi River basin, it has been introduced east of the Appalachian Mountains and into several western states. P. olivaris prefers the slow moving water of large rivers and lakes and can be spread by unintentional stock contamination of channel catfish shipments, but in most cases, it has been intentionally stocked.

view this species on IUCN Red List

Species Description
FWC (UNDATED) describes *P. olivaris* as having a flattened head, tiny eyes, a squarish tail and a protruding lower jaw that distinguishes *P. olivaris* from other catfish and contributes to it being placed in a genus of its own. This protuding lower jaw is an important characteristic when identifying the species (PFBC, 2003). They are yellow-brown and usually mottled above, with a creamy-white or yellow belly. *P. olivaris* can achieve weights of over 45kg but most weigh 1 to 7kg (FWC, UNDATED).

Uses
FWC (UNDATED) indicates that *P. olivaris* is highly regarded as a food fish when taken from clean water.

Habitat Description
According to PFBC (2003), *P. olivaris* is found in large rivers, streams, and lakes, usually over hard bottoms. They prefer deep, sluggish pools, with logs and other submerged debris that can be used as cover. Young *P. olivaris* live in rocky or sandy runs in the river and in riffles.

Reproduction
According to FWC (UNDATED), spawning occurs in late spring when water temperatures reach 21 to 27 degrees celsius. One or both parents excavate a nest that is usually made in a natural cavity or near a large submerged object. Females lay a golden-yellow mass of up to 100,000 eggs. Males guard the nest and agitate the eggs to keep them clean and aerated. The young remain in a school near the nest for several days after hatching, but soon disperse.

Nutrition
FWC (UNDATED) states that *P. olivaris* is a predatory fish and will consume bass, bream, shad, crayfish and often feed on other catfish. The young rely more extensively on aquatic insects and crayfish than do the adults. They rarely eat dead or decaying matter.

General Impacts
Many feeding studies have found that *Pylodictis olivaris* prey heavily on sunfish (*Lepomis* spp.). One study also found that they reduced the number of common carp (*Cyprinus carpio*) and bullheads (*Ameiurus* spp.). However, the introduced population in the Flint River system was found to prey largely on crayfish, and it was also found that young-of-the-year *P. olivaris* fed on darters (*Etheostoma* spp.) clupeids, catostomids, ictalurids, and centrarchids. A severe decline in native fish species, particularly native bullhead species, was observed in the Cape Fear River within 15 years of the first *P. olivaris* introduction.
One ichthyologist believes that of all fish introductions in North America, introductions of flathead catfish, are possibly the most biologically harmful (Carter Gilbert., pers. comm., in Fuller 2000).

Management Info
Preventative measures: The use of potentially invasive alien species for aquaculture and their accidental release/or escape can have negative impacts on native biodiversity and ecosystems. Hewitt *et al*, (2006) Alien Species in Aquaculture: Considerations for responsible use aims to first provide decision makers and managers with information on the existing international and regional regulations that address the use of alien species in aquaculture, either directly or indirectly; and three examples of national responses to this issue (Australia, New Zealand and Chile). The publication also provides recommendations for a 'simple' set of guidelines and principles for developing countries that can be applied at a regional or domestic level for the responsible management of Alien Species use in aquaculture development. These guidelines focus primarily on marine systems, however may equally be applied to freshwater.
Copp *et al*, (2005) Risk identification and assessment of non-native freshwater fishes presents a conceptual risk assessment approach for freshwater fish species that addresses the first two elements (hazard identification, hazard assessment) of the UK environmental risk strategy. The paper presents a few worked examples of assessments on species to facilitate discussion. The electronic Decision-support tools- Invasive-species identification tool kits that includes a freshwater and marine fish invasives scoring kit are made available on the Cefas (Centre for Environment, Fisheries & Aquaculture Science) page for free download (subject to Crown Copyright (2007-2008)).
Chemical: According to Sea Grant (2003), recent studies in Pennsylvania's Delaware Valley have been investigating *P. olivaris* physical and chemical sensitivities in hopes of finding a method of targeted removal, establishing selective barriers, or disrupting the spawning of the exotic species without harming native species. Researchers have discovered that *P. olivaris* exhibits a unique chemical sensitivity to the amino acid l-glutamine. After testing electrical responses of taste buds (or olfactory neurons) located on the skin and whiskers of the fish to 10 amino acids, it was determined that *P. olivaris*, unlike native channel catfish (*Ictalurus punctatus*), was most sensitive to l-glutamine.

Pathway
The flathead catfish has been intentionally stocked in most cases (Fuller, 2000).

Trinational Risk Assessment Guidelines for Aquatic Alien Invasive Species. Commission for Environmental Cooperation. 393, rue St-Jacques Ouest, Bureau 200, Montr&#65533;al (Qu&#65533;bec), Canada. ISBN 978-2-923358-48-1.
Summary: In 1993, Canada, Mexico and the United States signed the North American Agreement on Environmental Cooperation (NAAEC) as a side agreement to the North American Free Trade Agreement (NAFTA). The NAAEC established the Commission for Environmental Cooperation (CEC) to help the Parties ensure that improved economic efficiency occurred simultaneously with trinational environmental cooperation. The NAAEC highlighted biodiversity as a key area for trinational cooperation. In 2001, the CEC adopted a resolution (Council Resolution 01-03), which created the Biodiversity Conservation Working Group (BCWG), a working group of high-level policy makers from Canada, Mexico and the United States. In 2003, the BCWG produced the &#65533;Strategic Plan for North American Cooperation in the Conservation of Biodiversity.&#65533; This strategy identified responding to threats, such as invasive species, as a priority action area. In 2004, the BCWG, recognizing the importance of prevention in addressing invasive species, agreed to work together to develop the draft CEC Risk Assessment Guidelines for Aquatic Alien Invasive Species (hereafter referred to as the Guidelines). These Guidelines will serve as a tool to North American resource managers who are evaluating whether or not to introduce a non-native species into a new ecosystem. Through this collaborative process, the BCWG has begun to implement its strategy as well as address an important trade and environment issue. With increased trade comes an increase in the potential for economic growth as well as biological invasion, by working to minimize the potential adverse impacts from trade, the CEC Parties are working to maximize the gains from trade while minimizing the environmental costs.
