

Nassella neesiana [简体中文](#) [正體中文](#)

System: Terrestrial

| Kingdom | Phylum | Class | Order | Family |
|---------|---------------|------------|-----------|---------|
| Plantae | Magnoliophyta | Liliopsida | Cyperales | Poaceae |

| | |
|------------------------|---|
| Common name | Chilean needle grass (English) |
| Synonym | <i>Stipa neesiana</i> , Trin. & Rupr. |
| Similar species | <i>Nassella trichotoma</i> , <i>Nassella charruana</i> , <i>Nassella hyalina</i> , <i>Nassella lecotricha</i> , <i>Nassella tenuissima</i> |
| Summary | <i>Nassella neesiana</i> (Chilean needle grass) threatens the ecological integrity of affected natural ecosystems and also causes significant devastation in agricultural areas due to the reduction in pasture palatability and also direct damage to stock. |

[view this species on IUCN Red List](#)

Species Description

Perennial tussock forming C3 grass of up to 1m high. Flat leaves 1-5mm diameter, strongly ribbed on adaxial surface with rough margins. Inflorescence an open panicle; stem seeds (cleistogenes) are also produced (Gardner, 1998).

Notes

Nassella neesiana was previously known as *Stipa neesiana*. It is difficult to distinguish from native *Stipas*.

Lifecycle Stages

Peak flowering of Chilean needle grass in Australia occurs between November and February (Gardner, 1998), however it has the ability to flower all year round (Ens, 2002). The seed bank has been estimated to potentially persist in the soil for up to 12 years even with annual glyphosate application (Bourdote and Hurrell 1992)!

Uses

Good stock feed during winter only

Habitat Description

In Australia it invades disturbed grasslands and grassy woodlands of temperate regions with more than 500mm rainfall (Gardner, 1998)

Reproduction

Reproduces by sexual (chasmogamous) and asexual (cleistogamous) seed production. The cleistogenes are formed in the leaf sheaths and culms while the chasmogenes are found in the inflorescence (Gardner, 1998). Up to 22,000 chasmogamous seeds/plant/year can be produced (Bourdote and Hurrell 1992). Production of the asexual seeds is a common response following slashing, grazing or fire (Gardner, 1998).

General Impacts

Nassella neesiana has the tendency to replace native flora (Agriculture and Resource Management Council of Australia and New Zealand *et al.*, 2000; Ens, 2002), reduce ant abundance and alter the entire invertebrate community composition in conservation areas (Ens, 2002). Potential distribution overlaps an array of threatened species in Australia (Thorpe and Lynch, 2000). Agricultural productivity is thwarted by the replacement of palatable ground cover, injury to stock, reduction of produce quality and increased management costs (Thorpe and Lynch, 2000). Some sheep graziers in eastern Australia have been forced to switch to beef production (Thorpe and Lynch, 2000).

Management Info

Preventative measures: A combination of chemical, mechanical, rehabilitation, competition, grazing management, biological control techniques and hygiene regimes are required to eradicate Chilean Needle Grass (Agriculture and Resource Management Council of Australia and New Zealand *et al.*, 2000). As yet there is an absence of an effective herbicide (Agriculture and Resource Management Council of Australia and New Zealand *et al.* 2000).
